ABSTRACT
Nowadays, real estate organizations manage large volumes of sensitive and regulated documents related to property ownership, lease agreements, customer identification documents, valuation reports, and legal contracts by using Enterprise Content Management (ECM) systems that incur higher Operating Expenses and face challenges like document retrieval, knowledge discovery, governance, and regulatory compliance. Major software vendors provide robust software to manage digital strategy and a framework to organize, store, and secure customer-centric documents. As the customer base increases, document retrieval, operational efficiency, and knowledge discovery affect the performance of the applications. To eliminate these issues, the use of Artificial Intelligence (AI), Large Language Models (LLMs), and Retrieval-Augmented Generation (RAG) enables well-organized search and retrieval of information with enhanced application performance by using indexing of data from different sources. At the same time, AI-based technologies bring challenges concerning data privacy, regulatory compliance, governance, explainability, and security. The study presents Enterprise Architecture (EA) with an AI Governance Framework aimed at enabling regulatory-based Intelligent Enterprise Content Management (IECM) systems in real estate organizations. By combining EA principles and an AI governance control framework, it helps organizations manage customer-related documents, including regulatory compliance requirements and Personally Identifiable Information, in a controlled manner with a secure, transparent, and auditable platform. The proposed framework compares the traditional ECM with IECM architecture. Along with this, the paper presents how the transformation from the existing ECM to AI-based document search using RAG improves document retrieval by eliminating traditional search mechanisms, keywords, metadata, and folder hierarchies.

Keywords
Enterprise Architecture, AI Governance, Intelligent Document Management, Real Estate, RAG, Generative AI, Regulatory Compliance, PDPL, Information Governance.

1. INTRODUCTION
Real estate organizations manage large amounts of content related to images, rich media, audio, video, creative design files, text documents, brochures, legal agreements, users' personal information, data like passports, and other identification documents. Organizations must manage the documents in the appropriate software to comply with regulations and avoid auditing issues and heavy penalties. Most project teams do not manage the digital assets in the right systems. Project teams must understand when to use ECM and Document Asset Management (DAM) based on the asset sensitivity. The table 1 below represents the key differences between the ECM and DAM systems to manage in projects, as both systems store files but serve different needs and workflows.

Table 1: Comparison between ECM and DAM

Feature	ECM	DAM
Primary Content	PDFs, Legal documents, and PII documents	Rich media, Images, Video, Audio, 3D files, and Creative design
Used Departments	Legal, HR, Finance, and Compliance	Marketing, Creative agencies, and Branding
Primary Goal	Regulatory compliance, Data security, Retention rules, and Process automation	Brand consistency, enable fast creative collaboration, and simplify media reuse.
Search & Metadata	Basic text search, document IDs, and Index fields.	Deep visual previews, AI tagging, Keywords, and Rich Media metadata
Integration Systems	ERP, CRM, and HR systems	Design Platforms, CMS, and Social Publishing tools.

The ECM system's core capabilities include content capture, Document storage & organization, Search & retrieval using metadata, Workflow automation, Versioning, Role-based access, and Systems Integration. Real estate organizations predominantly utilize both ECM and DAM systems, as per the nature of the workflow in the project flow. Property management systems typically manage a high volume of documents throughout the lifecycle, including customer identity documents, title deeds, lease agreements, valuation reports, contracts, and regulatory-related documents. These documents are managed by ECM platforms that provide centralized storage, metadata management, workflow automation, retention controls, and document security. Managing ECM systems faces several challenges, like document volume, repository size, issues in indexing & metadata, regulatory constraints for customer data, limited document usage visibility, and lack of AI governance. Current ECM systems in the market address the workflow requirements but lack AI governance, AI capabilities, and EA alignment. To address the key challenges associated with IECM governance on AI, the investigative study was performed with pre-described questions used in Section 3. This paper proposes an IECM solution to enable semantic search, contextual search,

content classification, knowledge discovery, and conversational interaction leveraging Gen AI and Retrieval-Augmented Generation (RAG) technologies.

This paper is organized as follows: Section II describes the Literature Review, Section III compares the ECM and IECM Architecture, Section IV describes the EA & AI Governance Framework for the IECM, and Section V presents Conclusions and Further Work.

2. LITERATURE REVIEW

A survey was conducted with 300 industry professionals, along with a case study from Better Homes in leading UAE property management, using a mixed-methods approach to examine how AI helps to optimize work automation, data analysis, predictive maintenance, tenant interaction, operational effectiveness, and risk management using the Technology Acceptance Model (TAM) and Resource-Based View (RBV) [1]. Proposed comprehensive Enterprise Content Management System (ECMS) adoption improves transparency, accountability, information quality, and process integrity in systems, reducing corruption in Saudi Arabia's public financial sector with frameworks UTAUT (Unified Theory of Acceptance and Use of Technology), DeLone & McLean IS Success Model, and TOE Framework (Technology–Organization–Environment) [2]. Investigated how organizations adopted the ECM frameworks along with Agile Business Process to improve the suitability of ECM to reduce underutilization and misalignment of business processes [3]. The author proposed a modular AI ECM framework using Machine Learning (ML) and Natural Language Processing (NLP), along with privacy-preserving techniques in finance and healthcare domains by enabling scalable architecture, intelligent automation, high accuracy, secure governance, and optimization [4]. Proposed data science and AI technologies redesign the public administration concept with information systems, vertical functional allocations, and horizontal integrations by extending the Digital Governance Authority [5]. Comparative analysis was done on Novaland and Hung Thinh real estate firms by using the Strengths, Weaknesses, Opportunities, and Threats matrix and proposed strategic recommendations for sustainable rapid development [6]. A maturity governance checklist framework was developed after studying 115 peer-reviewed papers spanning 2010 to 2023 on AI, Internet of Things (IoT) in buildings, shared utilities, and industrial park operations in the real estate domain, with core capabilities – sustained observability, interpretability via open protocols, semantic models, edge-first, effective controllability, cloud adoption, integration models, and governance [7]. A survey was conducted with 330 respondents, reached via emails, social media, and direct phone calls; a t-test was performed on the variables Search Engine Optimization (SEO), Social Media Marketing (SMM), Content Marketing (CTM), and E-mail Marketing (EMM) to test the formulated hypothesis. The results show that by 2026, UAE real estate marketing has matured into an integrated and mature digital system, where social media marketing drives high-intent sales and immersive satisfied user trust [8]. Proposed AI-based transformations by enabling automation, improved decision-making, and new business models for developing robust, ethical, and expandable AI systems in Insurance and Real Estate domains, but the challenges remain in data quality, interpretability, regulation, and integration [9]. Collected and analyzed regulatory requirements for 40 documents across the EU, US, and Asia-Pacific regions that help the business and IT professionals' teams to understand the different AI governance frameworks and gaps at the implementation stage [10]. Presented paper on structured ECM along with a Data Governance framework implemented in an imaginary company, Teleware, as a case study, and addresses data integration, Data quality, Accessibility, and Regulatory compliance challenges [11]. The paper highlights that Document Management Systems (DMS) are considered for green digital transformation, and the author proposes that an organization's maturity significantly influences the DMS life cycle through the Process and Enterprise Maturity Model (PEMM); finally, the study shows that organizations with higher maturity levels manage DMS life cycles more effectively, supporting digital transformation and sustainability [12]. Evaluated the digital content quality, service quality, and communication effectiveness of ECM applications usage in Gulf information portals and how the ECM influences the communication services quality provided in digital portals [13]. Introduced a conceptual framework to develop AI governance-aware agents into real estate intelligence systems to ensure trust, accountability, transparency, and robustness in high-stakes real estate decision environments [14]. Conducted a study on 656 Scopus-indexed articles on how corporate governance research in the Asia region has grown significantly, driven by crises, reforms, and globalization, taking into consideration a 20-year bibliometric map (2001 to 2021), with Identification of major themes, Influential authors and journals, Country and institutional contributions, and Deep insights from papers [15]. The author proposes an AI-driven Random Forest (RF) method that improves property price estimations in Real Estate firms by supporting more responsible, sustainable, and informed real estate decision-making [16]. The author studied Sharjah's heritage institutions' digital content and how the systems are managed, focusing on strategies, systems, manpower characteristics, and challenges, and identified key findings: lack of strategies, varied CMS tools, technical gaps, and limited experience with resources [17].

Existing studies focus more on traditional ECM systems, and some of them talk about AI-enabled ECM systems independently, with limited discussion of how RAG is utilized in the IECM architecture along with EA principles and AI governance controls. The section below talks about the IECM architecture by comparing traditional ECM applications, and the research questions are framed to formulate the EA and AI governance framework for IECM applications.

3. TRADITIONAL ECM VS IECM ARCHITECTURE

Recent changes and Agentic AI innovations, along with NLP, LLMs, and RAG technologies, create a new way of document management that addresses the key challenges in existing ECM platforms. These AI technologies enable context-aware search, classification of documents, summarization of content, knowledge base creation, and semantic search. Organizations can improve document information accessibility by using vector indexing, embedding models, and Gen AI capabilities. Search functions in traditional ECMs primarily relay on metadata-based, contextual retrieval, document-centric, and data relationships. Major benefits of semantic search are high precision, classification, and faster discovery. ECM searches are very well suited to highly structured, well-organized document repositories and strict compliance frameworks. In real estate, organizations manage user-related data in document forms (user IDs, contracts, property records, legal agreements) in different systems like SharePoint, Azure Blob Storage, and ECM Systems. Retrieval of data from different systems is crucial, or performance is impacted as user data increases.

Traditional ECM architecture for Documents:

Most real estate organizations manage documents in multiple document repository systems like SharePoint, OpenText, Blob

Storage, and File systems. Documents are retrieved based on metadata tagging, folder hierarchies, and key-based searches. If any application user searches tenant information using search keywords - tenant, termination, and obligation the application returns the results based on metadata tags. Most of the project's problems with this approach were that results may be irrelevant, searches are time-consuming, and it requires domain knowledge. For example, the document repository has 50K documents containing Lease Agreements, Property Ownership Records, Valuation Reports, Compliance Documents, and the Personal Data Protection Law (PDPL) Policies in the ECM system. The user searches for documents containing personal information using "PDPL"; the search will display the policy documents uploaded in the ECM system with proper metadata. Searching a large amount of unstructured document content is a challenging part of traditional ECM systems. To achieve this, most projects adopt continuous monitoring of metadata quality, proper document relationship management, and domain knowledge building within the team. Below, Fig. 1 depicts the typical solution diagram for traditional ECM in the enterprise landscape.

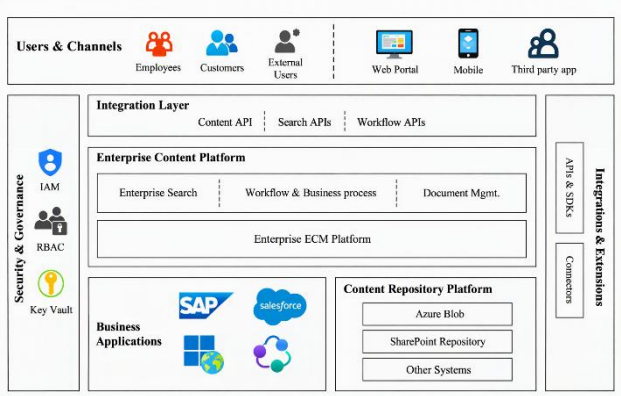

Fig. 1: Traditional ECM Architecture for Documents

IECM architecture for Documents:

Advancements in AI and LLMs create new Intelligent Enterprise Content Architecture systems to eliminate the problems observed in traditional ECM systems. RAG technology from AI enables document search more efficiently by enabling the following features

- Semantic search
- Contextual document retrieval
- Classification of content
- Content summarization
- Extraction of information
- Knowledge base creation & discovery
- Interaction with enterprise documents

Proposing an Intelligent Enterprise Content Management architecture for enabling content discovery by combining GenAI, RAG, and EA principles. The target architecture enables the following features.

- Document retrieval accuracy by using semantic search.
- Knowledge discovery by using RAG.
- EA & AI governance controls.
- Metadata-driven searches are reduced.
- Improves operational efficiency
- Future-ready, scalable architecture for AI-enabled document management systems.

In the proposed solution, RAG splits the documents into smaller portions to improve retrieval accuracy. Taking into consideration the above example described in the As-Is section, 50K documents are divided into smaller chunks. If the user wants to search for a tenant termination agreement with a 60-day notice period from the 50K documents, the vector DB captures the meaning of the search rather than the exact match done in traditional document search. In this search, the vector, along with RAG, identifies that the words termination, cancel lease, and end tenancy are relevant to the search and performs the search in a semantic way. If the user asks for the search key as PDPL, the traditional way only retrieves the data from metadata described in the As-Is section. In the IECM architecture, RAG retrieves data from chunks in a semantic way and displays the document with details like Passport copy, Government ID, Email Address, Phone Number, and Customer Profile. RAG provides compliance benefits such as Data residency, role-based access control, Source document linkage, Data exposure reduction, and Audit trails. Fig. 2 depicts the typical solution diagram for IECM in an enterprise landscape.

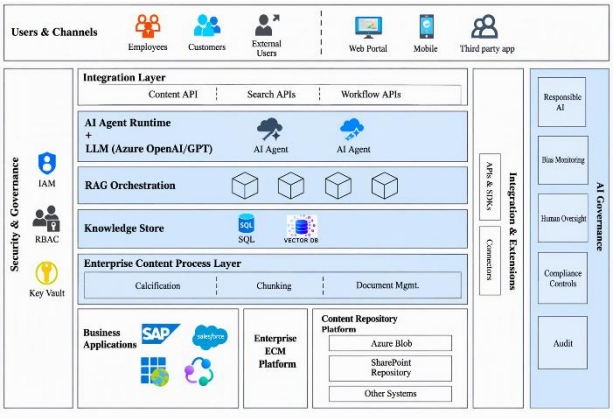

Fig. 2: IECM Architecture for Documents

Research studies were carried out to validate the IECM architecture along with AI governance & EA principles by answering the following questions derived from traditional ECM and capabilities of IECM architecture.

Question 1 – How do EA principles improve governance in the IECM system?

EA principles provide a structural approach aligning business processes, applications, and technology platforms in the organization's portfolio. Governance challenges are seen in the real estate organization for document search because the data is stored across multiple platforms. In this situation, EA establishes standardized integrations, metamodels, information flows, and governance to improve interpretability, scalability, and compliance management.

Question 2 – How do RAG and LLMs improve document retrieval and knowledge discovery compared to traditional ECM?

IECM architecture is developed using AI and LLM models to fetch documents, an internal core platform for RAG, and a vector database. RAG improves document retrieval, semantic content search (most relevant information), source document linkage, and document chunks.

Question 3 – How do the AI governance controls ensure secure, transparent, and compliant management of Personal Identifiable Information (PII) documents?

Establishing robust governance controls is very important, whether AI is enabled. The governance controls mitigate the risks associated with privacy and security in the document life cycle. Governance controls include RBAC, Human Oversight, Audit, Human-in-the-loop approval process, and regulatory compliance.

Question 4 – How does the IECM system support PDPL compliance while improving operational efficiency?

The system supports PDPL compliance by enforcing data access controls, document retention policies, sensitive data identification, and intensive audit trails. At the same time, operational efficiency was increased through:

- Faster retrieval of documents
- Content classification
- Knowledge base
- Improved search results extraction
- Contextual search for more accurate information fetching.

4. EA & AI GOVERNANCE FRAMEWORK FOR IECM

Adoption of AI, LLM, and RAG improves document retrieval, knowledge discovery, and operational efficiency within Enterprise Content Management (ECM) environments. However, the governance challenges related to privacy, security, explainability, regulatory compliance, accountability, and architectural consistency are not managed properly and lead to failure to meet business requirements. Fig. 3 represents the AI governance principles described.

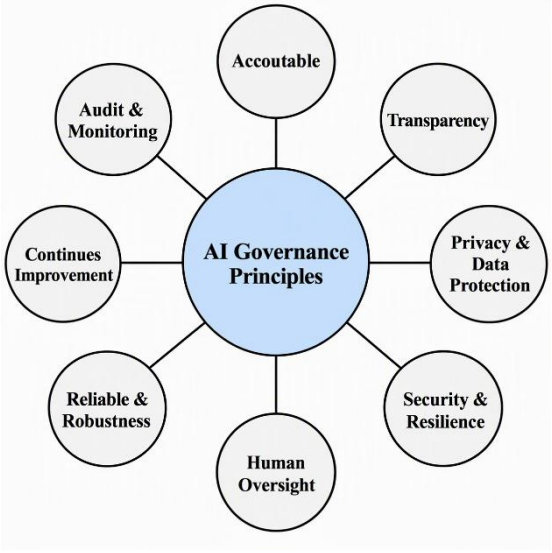

Fig. 3: AI Governance Principles

Addressing the challenges, this proposes a framework combining EA and AI Governance principles to establish secure, compliant, scalable, and intelligent document management. The framework aims to -

- AI-enabled ECM capabilities with business goals.
- Compliance with PDPL, privacy, and regulatory requirements.
- Improve document discovery and retrieval accuracy.
- Establish AI accountability and transparency.
- Protect sensitive customer information and PII.
- Enable continuous monitoring and governance of AI models.
- Enterprise-wide scalability, observability, and interoperability.

The EA & AI governance framework for IECM is not like traditional governance models that work independently; it proposes a new governance framework by integrating EA and AI governance frameworks and derives the following governance layers:

- Business Governance
- Information Governance
- EA Governance
- AI Governance
- Security and Compliance Governance
- Technology and Infrastructure

The integration of these layers together establishes the secure, transparent, scalable, and auditable IECM application. Fig. 4 represents the EA & AI governance framework with all layers.

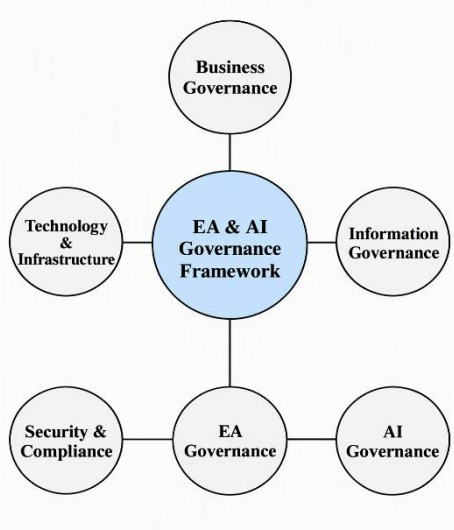

Fig. 4: EA & AI Governance Framework

Business Governance – Defines the business objectives, stakeholder responsibilities, compliance relationships, and realized value with IECM architecture. The business governance layer establishes sponsorship, committees, owners, performance indicators, and AI adoption strategies to support the business objectives of faster document search, improved customer services, regulatory compliance, and knowledge sharing.

Information Governance – Primarily manages the quality, lifecycle, ownership, accessibility, and usability of the document content. The information governance layer primarily governs data standards (while chunking), indexing policies, knowledge-based databases, and a trace of source documents to support the objectives of master data management, metadata management, and information lifecycle process.

EA governance – Without EA governance, the platforms become isolated between systems and inconsistent data flows. EA governance layer establishes architectural principles, standards, references, integrations, patterns, data flow models, and business alignment to achieve the scalability, modularity, security, and standardization of the IECM.

AI governance – AI systems operate ethically, transparently, and accountably due to the PII compliance of the user data in IECM systems. The key controls include human oversight, bias management, accountability, and traceability of events.

Security & Compliance governance – The framework protects sensitive information to ensure regular data compliance. Real estate organizations manage sensitive information like passport copies, government IDs, financials, property ownership, contracts, and agreements, which should be securely governed by implementing controls such as RBAC, data privacy using data masking, AI controls, and audit.

Technology & Infrastructure governance – Infrastructure scalability, reliability, observability, optimization, recovery, and cost management are key objectives for infrastructure governance. In the IECM architecture. The recommended solutions to achieve the key objectives are high availability architectures, container orchestration, monitoring, backup and

recovery, Infrastructure as Code (IaC), and security-by-design principles.

The governance layers defined above operate as an integrated ecosystem rather than independent governing systems. Integrating them all together provides a holistic governance model for any typical architecture. Interdependencies create an end-to-end governance chain where business objectives, information quality, architecture standards, AI accountability, regulatory compliance, and technology operations collectively support a secure and IECM platform. The framework enables real estate firms to improve document retrieval accuracy, enhance knowledge discovery, strengthen compliance management, and establish AI adoption. The cross-layer relationship between the layers defined in the EA & AI governance framework is depicted in Fig. 5.

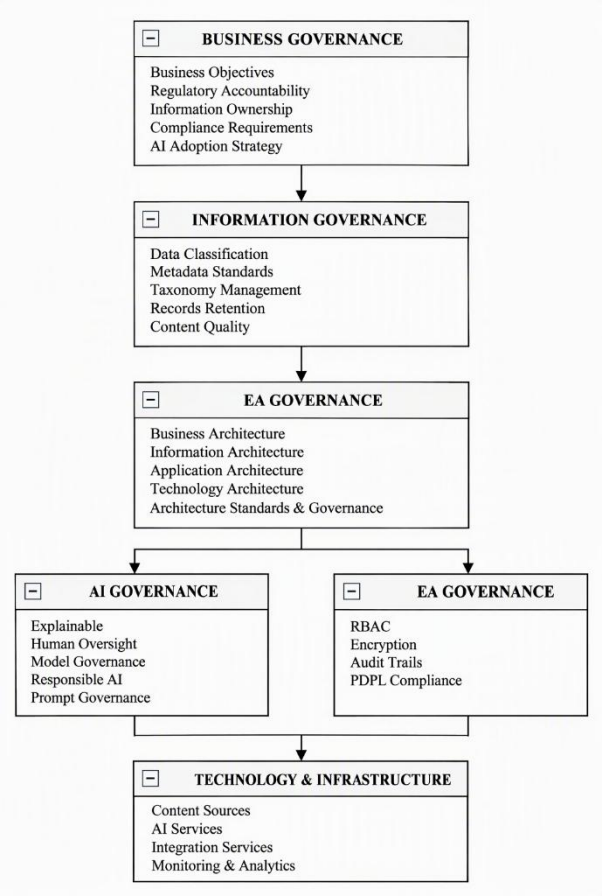

Fig. 5: Relationship between the layers

The framework delivers significant value to real estate organizations across business, architectural, and governance dimensions. From a business perspective, it enables faster customer document retrieval, enhances regulatory compliance, reduces operational costs, and promotes efficient knowledge reuse. Architecturally, it supports standardized information flows, improved interoperability, greater scalability, and the reduction of application silos. From a governance standpoint, the framework strengthens auditability and traceability, ensures AI accountability, and facilitates effective risk mitigation.

5. CONCLUSION

Real estate organizations manage sensitive documents such as property ownership records, lease agreements, customer identification documents valuation reports, contracts, and compliance-related documentation are stored across multiple repositories and enterprise systems. Major challenges occur for retrieval and governance of documents while the Organizations expand their digital content. Traditional ECM systems provide essential features for managing content storage, workflow automation, and compliance, they primarily use metadata-based searches and rigid repository structures that hinder intelligent knowledge discovery and contextual information retrieval. To overcome the limitations of traditional ECM architecture and governance, this study introduced an IECM architecture that integrates Enterprise Architecture (EA) principles with Artificial Intelligence (AI), Large Language Models (LLMs), and Retrieval-Augmented Generation (RAG) technologies. This architecture illustrates how semantic search, contextual retrieval, content classification, knowledge discovery, and conversational interaction can improve document accessibility and operational efficiency while adhering to regulatory requirements. The research shows that technology adoption is not enough to achieve sustainable, reliable intelligent document management. Effective governance is equally critical for controls that are used in AI to address accountability, transparency, explainability, human oversight, auditability and role-based access management to ensure the secure and ethical management of sensitive information, including Personally Identifiable Information (PII).

This paper suggested an integrated framework for governance in the face of emerging governance challenges, with six interrelated governance layers: Business Governance, Information Governance and Enterprise Architecture Governance; AI Governance); Security and Compliance Governance (S&C), and Technology and Infrastructure Governance. These layers function as a single governance ecosystem that fosters strategic alignment, information quality, architectural consistency (decision making), compliance with regulations and the digital revolution; operational resilience and continuous improvement. The suggested framework serves as a reference model for organizations to update their document management systems while maintaining interdisciplinary collaboration with governance. This offers an opportunity for real estate firms to improve customer experience, strengthen compliance management, enhance knowledge utilization and help with future digital transformation initiatives by leveraging AI-powered content management capabilities seamless manner.

Validation of the proposed framework through extensive industry implementations and empirical case studies across different real estate is a crucial aspect of future research. Additional themes to examine are the incorporation of Agentic AI features, advanced artificial intelligence governance maturity models (AIGs), cross-jurisdictional regulatory compliance requirements, digital twins and enterprise knowledge graph integration with trustworthy and explainable AI mechanisms, performance benchmarking of IECM platforms, and business value realization measurement. Intelligent Enterprise Content Management will become more defined by the convergence of several key areas: Enterprise Architecture, AI Governance, Agentic AI, knowledge-driven ecosystems and responsible AI practices; and enables organizations to build intelligent, compliant, and future-ready content management environments that are component to changing AI technologies.
